```
##Grades
```

Q1. Write a function grade() to determine an overall grade from a vector of student homework assignment scores dropping the lowest single score. If a student misses a homework (i.e. has an NA value) this can be used as a score to be potentially dropped. Your final function should be adquately explained with code comments and be able to work on an example class gradebook such as this one in CSV format: "https://tinyurl.com/gradeinput"

```
# Example input vectors to start with student1 <- c(100, 100, 100, 100, 100, 100, 100, 90) student2 <- c(100, NA, 90, 90, 90, 90, 97, 80) student3 <- c(90, NA, NA, NA, NA, NA, NA, NA)
```

Finding the mean for student 1

```
mean(student1)
```

[1] 98.75

The issue with mean(student1) is that this does not work with vectors that contain 'NA'

```
mean(student2, na.rm = TRUE)
```

[1] 91

Trying this code on student3

```
mean(student3, na.rm = TRUE)
```

[1] 90

The issue with this is that it completely removes all the NAs instead of just one NA

We can replace the missed assignment NA values with a score of zero. - How can I do this? -First I need to find where the NA values are?

We can use is.na() function to help perhaps?

```
student2
[1] 100 NA 90 90 90 90 97 80
is.na(student2)
```

[1] FALSE TRUE FALSE FALSE FALSE FALSE FALSE

We call out which one is "True" and set it equal to 0

```
student2[is.na(student2)] <- 0
student2

[1] 100  0  90  90  90  90  97  80</pre>
```

To save the original vector, we will set the original vector to x and use it to find replace all the NA to 0.

```
x <- student3
x[is.na(x)] <- 0
mean(x)</pre>
```

[1] 11.25

Finally, we want to drop the lowest score before calculating the mean. This is equivalent to allowing the students to drop their worst assignment score.

--which.min() drops the lowest score

```
x <- student1
```

[1] 100 100 100 100 100 100 100 90

```
which.min(x)
[1] 8
    x[-which.min(x)]
[1] 100 100 100 100 100 100 100
```

Now I need to put this all together to make out working snippet:

```
x <- student3

#Map/ replace NA values to zero
x[is.na(x)] <- 0

#Exclude the lowest score
x[-which.min(x)]

[1] 90 0 0 0 0 0 0

#Calculate the mean
mean(x[-which.min(x)])</pre>
```

[1] 12.85714

Cool! This is my working snippet that I can turn into a function called grade() All functions in R have at least 3 things:

- Name, in our case "grade"
- Input arguments, students1 etc.
- Body, this is our working snippet above.

```
grade <- function(x) {

#Map/replace NA values to zero
x[is.na(x)] <- 0</pre>
```

```
#Exclude the lowest score and calculate the mean
  mean(x[-which.min(x)])
  }
Can I use the function now?
  grade(student1)
[1] 100
  grade(student2)
[1] 91
  grade(student3)
[1] 12.85714
Read a gradebook from online:

```

We can use the apply() function to grade all the students in this class with our new grade() function.

The apply() function allows us to run any function over whether the rows or column of a data.frame. Let's see how this works.

sidenote: apply(data, margin = 1 (row) or 2 (column), function)

```
ans <- apply(hw, 1, grade)
ans</pre>
```

```
student-4
                                               student-5
 student-1
